BOOST YOUR CONFIDENCE (INTERVALS) WITH SAS

Brought to you by:

Peter Langlois, PhD Birth Defects Epidemiology & Surveillance Branch, Texas Dept State Health Services Background

Confidence Interval Definition

 DEFINITION: An interval around a statistic that contains the true underlying value of the statistic (the population parameter) a certain amount of the time

Confidence Interval Definition

 Example: a survey of 50 SAS programmers finds that the average IQ is 130 <u>+</u> 10

 If we did 100 surveys, the average IQ should be between 120 and 140 in 95 of them

Confidence Interval Definition

 95% confidence interval bounded by the upper 95% confidence limit and the lower 95% confidence limit

- 95% just conventional. Can have for e.g.: – 90% CIs (narrower)
 - 99% CIs (wider)
- CI for any level (95% etc) is narrower if based on more observations

General Formula

- Can make CIs around almost any statistic you calculate, for example...
- Data summaries (1 var) such as:
 Categorical variables: proportion
 Continuous variables: mean
- Statistics resulting from hypothesis tests (2+ vars):
 - Correlation, regression slope
 - Relative risk, odds ratios

Using Confidence Intervals

Why Use Cls?

- Gives audience idea of impact of chance
- Gives reasonable bounds on your result(s)
- Can check if your data are compatible with a certain value
 - (From data summary): Does 95% confidence interval of IQ in SAS programmers include 100?
 - (From hypothesis testing): Is occurrence of schizophrenia higher in SAS programmers or SPSS users? (Does relative risk = 1.00?)

Why Not Use Cls?

• Some organizations consider their figures to be a census, not a sample

• Increases statistical work for staff

 Some data users may find the concept confusing

Overlapping Cls vs Hypothesis Tests

- Example: Want to compare prevalence of schizophrenia in SAS vs SPSS users
- You could:
 - (A) Calculate schizophrenia prevalence and 95% CI for each group and see if overlap OR
 - (B) Calculate prevalence ratio of one group vs another, and see if includes 1.00

Overlapping Cls vs Hypothesis Tests

- Answer: (B) usually better
- Why? More statistical power

- Why even consider the first approach?
 - Easier to do if already have data summaries published
 - Can't anticipate all comparisons readers will want to make

Confidence Intervals For Data Summaries

CIs for Means

- Based on normal distribution
- Where your study sample is large (# of subjects > 30), the sampling distribution → normal, and you can use:

CI = obsd mean <u>+</u> 1.96 X standard error (of mean) = obsd mean <u>+</u> 1.96 X standard dev'n / sqrt(n)

$$= \overline{x} \pm 1.96 \frac{s}{\sqrt{n}}$$

Cls for Means: Using SAS

• Let SAS do it!

• Recall: Using SAS for simple desc stats:

proc means;
 var <variable name>;

Cls for Rates of Rare Outcomes

Follows Poisson distribution

Standard error based on number of cases

Cls for Rates of Rare Outcomes PREVALENCE BASED ON < 30 CASES

- Find upper and lower 95% conf limits for # cases:
 - In table (e.g. poisson.xls)
 - Using PEPI program POISSON

 Multiply both by (10000) and divide by # population or live births to express as birth prevalence

CIs for Rates of Rare Outcomes

EXAMPLE

- # cases of anophthalmia in CA 1983-1986 = 18
- Prevalence = (18 * 10,000 / 452,287) = 0.40
- Looking in table, lower 95% CL is 10.67 and upper 95% CL is 28.45 for # cases
- To express as prevalence CLs, multiply both by 10,000 and divide by 452,287 live births
- Lower 95% CL = 0.24, upper 95% CL = 0.63
- Thus we say prev = 0.40 cases per 10,000 live births, 95% CI = 0.24 - 0.63

Cls for Rates of Rare Outcomes PREVALENCE BASED ON 30+ CASES

• Considered large # cases (more or less)

- Poisson → normal distribution
- Can use normal approximation in SAS code
- Several equations for doing this, yielding similar results

Cls for Rates of Rare Outcomes

 SAS code for obs with few cases: Combine with Poisson lower and upper limits for cases (get lfactor and ufactor for the observed # cases):

```
proc sort data=b1; by count;
```

```
proc sort data=lib2.poisson out=poisson;
    by count;
```

```
data c1 prob2;
merge b1(in=b) poisson(in=p);
by count;
if b;
```

CIs for Rates of Rare Outcomes

 SAS code: Calculate CIs for obs with many cases too

```
data c2;
 set c1;
 calcrate = count * 10000 / births;
 if count le 30 then do;
   calclcl = lfactor * 10000 / births;
   calcucl = ufactor * 10000 / births;
   end;
 else if count > 30 then do;
   calclcl = ((count / births) - (1.96 * sqrt(count) / births)) * 10000;
   calcucl = ((count / births) + (1.96 * sqrt(count) / births)) * 10000;
   end;
 rate = round(calcrate,.01);
 lcl = round(calclcl,.01);
 ucl = round(calcucl,.01);
 rename count=cases;
```

Reminder

 To compare groups (e.g. whether rates are statistically different), can calculate 95% confidence intervals and see if they overlap

Better to do hypothesis testing

Confidence Intervals For Statistics From Hypothesis Tests / Measures of Association

Types of Hypothesis Tests / Measures of Association

| Indep Var | Dep Var | Approach (SAS PROC) |
|--------------|-------------|--|
| Categorical | Categorical | Contingency tables (FREQ) |
| Cat. / Cont. | Categorical | Logistic reg. (LOGISTIC) |
| Categorical | Cont. | ANOVA (GLM); if 2 levels then T-test (TTEST or GLM) |
| Cont. | Cont. | Linear reg. (REG or GLM) |
| Cat. / Cont. | Rates | Poisson reg. (GENMOD) |

Contingency Tables Using SAS

 Recall: Using SAS to produce the basic 2x2 table:

proc freq;
 tables <indep var> * <outcome var>;

• To get odds ratios and their CIs, request measures of association:

proc freq;
 tables <indep var> * <outcome var>
 / measures;

Contingency Tables Using SAS

QUESTION: Is mother's education associated with % low birth weight babies?

- Independent variable = m_edu2g_v
- Outcome variable = lbw
- If no statistically significant association, 95% CI will include 1.00

proc freq; tables m_edu2g_v * lbw / measures;

Logistic Regression: Using SAS

- Can use PROC LOGISTIC in SAS; nice since it will exponentiate the slope (b) and its 95% confidence interval
- Basic syntax:

proc logistic; model <outcome var> = <independent var>;

For low birthweight example:
 proc logistic;
 model lbw = m_edu2g_v;

Logistic Regression: Using SAS

 (One way) to get correct odds ratio: declare independent var to be a classification (categorical) var:

```
proc logistic;
   class m_edu2g_v;
   model lbw = m_edu2g_v;
```

Logistic Regression: Using SAS

 Comparing results from PROC FREQ and PROC LOGISTIC:

| SAS Proc | OR | 95% CI |
|----------|--------|-----------------|
| FREQ | 1.0366 | 1.0122 – 1.0616 |
| LOGISTIC | 1.037 | 1.012 – 1.062 |

Logistic Regression With Multiple Predictor Variables

- Like other regression, the slope (b) is adjusted for all other independent variables in the model
- SAS takes both cont and categorical vars
 - SAS assumes ind vars are continuous
 - If categorical, list in CLASS statement and SAS creates dummy vars automatically

proc logistic;

class <categorical independent vars>;
model <dependent var> = <independent vars>;
